Abstract

Although there exist plentiful theories of empirical risk minimization (ERM) for supervised learning, current theoretical understandings of ERM for a related problem—stochastic convex optimization (SCO), are limited. In this work, we strengthen the realm of ERM for SCO by exploiting smoothness and strong convexity conditions to improve the risk bounds. First, we establish an
$\widetilde{O}\left(\quad + \sqrt{\quad_*\quad} \right)$

O

where $\mathbf{H} = \{ h : \mathbf{X} \mapsto \mathbb{R} \}$ is a hypothesis class, $(\mathbf{x}, y) \in \mathbf{X} \times \mathbb{R}$ is an instance-label pair sampled from a distribution $\mathbb{D}$, and $\ell(\cdot, \cdot) : \mathbb{R} \times \mathbb{R} \mapsto \mathbb{R}$ is certain loss. In this paper, we mainly focus on the convex version of (1), namely stochastic convex optimization (SCO), where both the domain $\mathbf{W}$ and the expected function $F(\cdot)$ are convex.

Two classical approaches for solving stochastic optimization are stochastic approximation (SA) (Kushner and Yin, 2003) and the sample average approximation (SAA), the latter of which is also referred to as empirical risk minimization (ERM) in the machine learning community (Vapnik, 1998). While both SA and ERM have been extensively studied in recent years (Bartlett and Mendelson, 2002; Bartlett et al., 2005; Nemirovski et al., 2009; Moulines and Bach, 2011; Hazan and Kale, 2011; Rakhlin et al., 2012; Agarwal et al., 2012; Bach and Moulines, 2013; Zhang et al., 2013b; Mahdavi et al., 2015), most theoretical guarantees of ERM are restricted to supervised learning in (2). As pointed out in a seminal work of Shalev-Shwartz et al. (2009), the success of ERM for supervised learning cannot be directly extended to stochastic optimization. Actually, Shalev-Shwartz et al. (2009) have constructed an instance of SCO that is learnable by SA but cannot be solved by ERM. Literatures about ERM for stochastic optimization (including SCO) are quite limited, and we still lack a full understanding of the theory.

In ERM, we are given n functions $f_1, \ldots, f_n$ sampled independently from $\mathbb{P}$, and aim to minimize an empirical objective function:

$$\min_{\mathbf{w} \in \mathcal{W}} \widehat{F}(\mathbf{w}) = \frac{1}{n} \sum_{i=1}^{n} f_i(\mathbf{w}) \tag{3}$$

Let $\widehat{\mathbf{w}} \in \operatorname{argmin}_{\mathbf{w} \in \mathcal{W}} \widehat{F}(\mathbf{w})$ be an empirical minimizer. The performance of ERM is measured in terms of the excess risk defined as

$$F(\widehat{\mathbf{w}}) - \min_{\mathbf{w} \in \mathcal{W}} F(\mathbf{w})$$

State-of-the-art risk bounds of ERM include: an $\widetilde{O}(\sqrt{d/n})$ bound when the random function $f(\cdot)$ is Lipschitz continuous,[1] where d is the dimensionality of $\mathbf{w}$; an $O(1/\lambda n)$ bound when $f(\cdot)$ is λ-strongly convex (Shalev-Shwartz et al., 2009); and an $\widetilde{O}(d/n)$ bound when $f(\cdot)$ is β-exponentially concave (β-exp-concave) (Mehta, 2016). From existing studies of ERM for supervised learning (Srebro et al., 2010), we know that smoothness can be utilized to boost the risk bound. Thus, it is natural to ask whether smoothness can also be exploited to improve the performance of ERM for SCO. This paper provides an affirmative answer to this question. Indeed, we propose a general approach for analyzing the excess risk of ERM, which brings several improved risk bounds and new risk bounds as well.

To state our results, we first introduce some notations. Let $F_* = \min_{\mathbf{w} \in \mathcal{W}} F(\mathbf{w})$ be the minimal risk, λ be the modulus of strong convexity of $F(\cdot)$ and L be the modulus of smoothness of $F(\cdot)$. Denote by $\kappa = L/\lambda$ the condition number of the problem. Our and previous results of ERM for SCO are summarized in Table 1, where we make explicit the assumptions on the random function $f(\cdot)$, the empirical function $\widehat{F}(\mathbf{w})$ and the expected function $F(\cdot)$. For our results of ERM for SCO, we assume the domain is bounded, and the random function is nonnegative. We highlight the significance of this work as follows:

---

1. We use the $\widetilde{O}$ and $\widetilde{\Omega}$ notations to hide constant factors as well as polylogarithmic factors in d and n.

Table 1: Summary of Excess Risk Bounds of ERM for SCO. All bounds hold with high probability except the one marked by *, which holds in expectation. Abbreviations: bounded $\to$ b, convex $\to$ c, generalized linear $\to$ gl, Lipschitz continuous $\to$ Lip, nonnegative $\to$ nn, strongly convex $\to$ sc, smooth $\to$ sm, η-exponentially concave $\to$ η-exp.

	$\ell(\cdot)$	$\widehat{\ell}(\cdot)$	$r(\cdot)$	Risk Bounds
Shalev-Shwartz et al. (2009)	Lip	-	-	$\widetilde{O}\left(\sqrt{\frac{d}{n}}\right)$
	Lip & sc	-	-	$\left(\frac{1}{\lambda n}\right)^*$
Mehta (2016)	η-exp & Lip & b	-	-	$\widetilde{O}\left(\frac{d}{\eta n}\right)$
This work — Theorem 1	nn & c & sm	-	Lip	$\widetilde{O}\left(\frac{d}{n}+\sqrt{\frac{F_*}{n}}\right)$
Theorem 3	nn & c & sm	-	Lip & sc	$\widetilde{O}\left(\frac{d}{n}+\frac{\kappa F_*}{n}\right)$ $\left(\frac{1}{\lambda n^2}+\frac{\kappa F_*}{n}\right)$ when $\lambda=\widetilde{\Omega}(\kappa)$
Theorem 5	nn & sm	c	sc	$\widetilde{O}\left(\frac{\kappa d}{n}+\frac{\kappa F_*}{n}\right)=\widetilde{O}\left(\frac{\kappa d}{n}\right)$ $\left(\frac{1}{\lambda n^2}+\frac{\kappa F_*}{n}\right)$ when $\lambda=\widetilde{\Omega}(\kappa^2)$
Theorem 7	nn & sm & gl	c	sc	$\left(\frac{\kappa}{n}+\frac{\kappa F_*}{n}\right)=\left(\frac{\kappa}{n}\right)$ $\left(\frac{1}{\lambda n^2}+\frac{\kappa F_*}{n}\right)$ when $\lambda=\Omega(\kappa^2)$

- When $\ell(\cdot)$ is both convex and smooth and $r(\cdot)$ is Lipschitz continuous, we establish an $\widetilde{O}\left(\frac{d}{n}+\sqrt{\frac{F_*}{n}}\right)$ risk bound (c.f. Theorem 1). In the optimistic case that F_* is small, i.e., $F_*=O\left(\frac{d^2}{n}\right)$, we obtain an $\widetilde{O}\left(\frac{d}{n}\right)$ risk bound, which is analogous to the $\widetilde{O}(1/n)$ optimistic rate of ERM for supervised learning (Srebro et al., 2010).
- If $r(\cdot)$ is also λ-strongly convex, we prove an $\widetilde{O}\left(\frac{d}{n}+\frac{\kappa F_*}{n}\right)$ risk bound, and improve it to $\left(\frac{1}{\lambda}[\frac{\kappa}{n^2}]+\frac{\kappa F_*}{n}\right)$ when $\lambda=\widetilde{\Omega}(\kappa)$ (c.f. Theorem 3). Thus, if λ is large and F_* is small, i.e., $F_*=O(1/\lambda)$, we get an $O\left(\frac{\kappa}{\lambda n^2}\right)$ risk bound, which to the best of our knowledge, is the first $(1-\eta^2)$-type of risk bound of ERM.
- When convexity is not present in $\ell(\cdot)$, as long as $\ell(\cdot)$ is smooth, $\widehat{\ell}(\cdot)$ is convex and $r(\cdot)$ is strongly convex, we still obtain an improved risk bound of $\left(\frac{1}{\lambda}[\frac{\kappa}{n^2}]+\frac{\kappa F_*}{n}\right)$ when $\lambda=\widetilde{\Omega}(\kappa^2)$, which will further imply an $O\left(\frac{\kappa}{\lambda n^2}\right)$ risk bound if $F_*=O(1/\lambda)$ (c.f. Theorem 5).
- Finally, we extend the $\left(\frac{1}{\lambda}[\frac{\kappa}{n^2}]+\frac{\kappa F_*}{n}\right)$ risk bound to supervised learning with a generalized linear form. Our analysis shows that in this case, the lower bound of λ can be replaced with $\Omega(\kappa^2)$, which is dimensionality-independent (c.f. Theorem 7). Thus, this result can be applied to infinite dimensional cases, e.g., learning with kernels.

2. Related Work

In this section, we give a brief introduction to previous work on ERM.

2.1. ERM for Stochastic Optimization

As we mentioned earlier, there are few works devoted to ERM for stochastic optimization. When $\mathbf{W} \quad \mathbb{R}^d$ is bounded and $(\cdot)$ is Lipschitz continuous, Shalev-Shwartz et al. (2009) demonstrate that $\widehat{\ }(\mathbf{w})$ converges to $(\mathbf{w})$ uniformly over $\mathbf{W}$ with an $\widetilde{\ }(\sqrt{})$ error bound that holds with high probability, implying an $\widetilde{\ }(\sqrt{})$ risk bound of ERM. They further establish an $(1 \quad)$ risk bound of ERM that holds in expectation when $(\cdot)$ is -strongly convex and Lipschitz continuous. Stochastic optimization with exp-concave functions is studied recently (Koren and Levy, 2015),[2] and Mehta (2016) proves an $\widetilde{\ }(\quad)$ bound of ERM that holds with high probability when $(\cdot)$ is -exp-concave, Lipschitz continuous, and bounded. Lower bounds of ERM for stochastic optimization is investigated by Feldman (2016), who exhibits (i) a lower bound of $\Omega(\quad^2)$ sample complexity for uniform convergence that nearly matches the upper bound of Shalev-Shwartz et al. (2009); and (ii) a lower bound of $\Omega(\quad)$ sample complexity of ERM, which is matched by our $\widetilde{\ }(\quad + \sqrt{\quad_*})$ bound when $_*$ is small.

2.2. ERM for Supervised Learning

We note that there are extensive studies on ERM for supervised learning, and hence the review here is non-exhaustive. In the context of supervised learning, the performance of ERM is closely related to the uniform convergence of $\widehat{\ }(\cdot)$ to $(\cdot)$ over the hypothesis class $\mathbf{H}$ (Koltchinskii, 2011). In fact, uniform convergence is a sufficient condition for learnability (Shalev-Shwartz and Ben-David, 2014), and in some special cases such as binary classification, it is also a necessary condition (Vapnik, 1998). The accuracy of uniform convergence, as well as the quality of the empirical minimizer, can be upper bounded in terms of the complexity of the hypothesis class $\mathbf{H}$, including data-independent measures such as the VC-dimension and data-dependent measures such as the Rademacher complexity.

Generally speaking, when $\mathbf{H}$ has finite VC-dimension, the excess risk can be upper bounded by $(\sqrt{\mathrm{VC}(\mathbf{H})\ })$, where $\mathrm{VC}(\mathbf{H})$ is the VC-dimension of $\mathbf{H}$. If the loss $(\cdot \ \cdot)$ is Lipschitz continuous with respect to its first argument, we have a risk bound of $(1 \quad^{-} + \mathbf{R}_n(\mathbf{H}))$, where $\mathbf{R}_n(\mathbf{H})$ is the Rademacher complexity of $\mathbf{H}$. The Rademacher complexity typically scales as $\mathbf{R}_n(\mathbf{H}) = (1 \quad^{-})$, e.g., $\mathbf{H}$ contains linear functions with low-norm, implying an $(1 \quad^{-})$ risk bound (Bartlett and Mendelson, 2002). There have been intensive efforts to derive rates faster than $(1 \quad^{-})$ under various conditions (Lee et al., 1996; Panchenko, 2002; Bartlett et al., 2005; Gonen and Shalev-Shwartz, 2016), such as low-noise (Tsybakov, 2004), smoothness (Srebro et al., 2010), strong convexity (Sridharan et al., 2009), to name a few amongst many. Specifically, when the random function $(\cdot)$ is nonnegative and smooth, Srebro et al. (2010) have established a risk bound of $\widetilde{\ }(\mathbf{R}_n^2(\ ) + \mathbf{R}_n(\ )\ _*)$, reducing to an $\widetilde{\ }(1\ )$ bound if $\mathbf{R}_n(\mathbf{H}) = (1\ ^{-})$ and $_* = (1\ )$. A generalized linear form of (2) is studied by Sridharan et al. (2009), and a risk bound of $(1\ )$ is proved if the expected function $(\cdot)$ is -strongly convex.

3. Faster Rates of ERM

We first introduce all the assumptions used in our analysis, then present theoretical results under different combinations of them, and finally discuss a special case of supervised learning.

---

2. Their excess risk bound is for a regularized empirical risk minimizer.

3.1. Assumptions

In the following, we use $\|\cdot\|$ to denote the ℓ_2-norm of vectors.

Assumption 1 *The domain* **W** *is a convex subset of* $\mathbb{R}^d$, *and is bounded by* , *that is,*

$$\|\mathbf{w}\| \qquad \mathbf{w} \quad \mathbf{W} \tag{4}$$

Assumption 2 *The random function* $(\cdot)$ *is nonnegative, and* *-smooth over* **W**, *that is,*

$$\big\|\ (\mathbf{w}) -\ (\mathbf{w}')\big\| \qquad \|\mathbf{w} - \mathbf{w}'\| \qquad \mathbf{w}\ \mathbf{w}'\ \mathbf{W} \qquad \mathbb{P} \tag{5}$$

Assumption 3 *The expected function* $(\cdot)$ *is* *-Lipschitz continuous over* **W**, *that is,*

$$\big|\ (\mathbf{w}) -\ (\mathbf{w}')\big| \qquad \|\mathbf{w} - \mathbf{w}'\| \qquad \mathbf{w}\ \mathbf{w}'\ \mathbf{W} \tag{6}$$

Assumption 4 *We use different combinations of the following assumptions on convexity.*
  (a) *The expected function* $(\cdot)$ *is convex over* **W**.
  (b) *The expected function* $(\cdot)$ *is* *-strongly convex over* **W**, *that is,*

$$(\mathbf{w}) + \quad (\mathbf{w})\ \mathbf{w}' - \mathbf{w}\ + \frac{}{2}\ \|\mathbf{w}' - \mathbf{w}\|^2 \qquad (\mathbf{w}') \quad \mathbf{w}\ \mathbf{w}'\ \mathbf{W} \tag{7}$$

  (c) *The empirical function* $\widehat{}(\cdot)$ *is convex.*
  (d) *The random function* $(\cdot)$ *is convex.*

Assumption 5 *Let* $\mathbf{w}_* \quad \operatorname{argmin}_{\mathbf{w}\in\mathcal{W}}\ (\mathbf{w})$ *be an optimal solution to* ([1](#)). *We assume the gradient of the random function at* $\mathbf{w}_*$ *is upper bounded by* , *that is,*

$$(\mathbf{w}_*) \qquad\qquad \mathbb{P} \tag{8}$$

Remark 1 First, note that **Assumption 4(a)** is implied by either **Assumption 4(b)** or **Assumption 4(d)**, and **Assumption 4(c)** is implied by **Assumption 4(d)**. Second, the smoothness assumption of $(\cdot)$ implies the expected function $(\cdot)$ is -smooth. By Jensen's inequality, we have

$$\big\|\ (\mathbf{w}) -\ (\mathbf{w}')\big\| \quad \mathrm{E}_{f\sim\mathbb{P}}\big\|\ (\mathbf{w}) -\ (\mathbf{w}')\big\| \qquad \|\mathbf{w} - \mathbf{w}'\| \qquad \mathbf{w}\ \mathbf{w}'\ \mathbf{W}$$

Similarly, the empirical function $\widehat{}(\cdot)$ is also -smooth. The *condition number* of $(\cdot)$ is defined as the ratio between and , i.e., $=\qquad 1$.

3.2. Risk Bounds for SCO

We first present an excess risk bound under the smoothness condition.

Theorem 1 *For any* $0 \qquad 1\ 2,\qquad 0$, *define*

$$(\ ) = 2\left(\log\frac{2}{} +\ \log\frac{6}{}\right) \tag{9}$$

5

Under **Assumptions** **1**, **2**, **3**, **4(d)**, *and* **5**, *with probability at least* $1 - 2\delta$, *we have*

$$\mathcal{R}(\widehat{\mathbf{w}}) - \mathcal{R}(\mathbf{w}_*)$$

$$\frac{16\beta^2(\,\cdot\,)}{\,} + \frac{8\beta\log(2\,\cdot\,)}{\,} + 8\sqrt{\frac{2\,\cdot\,_*\log(2\,\cdot\,)}{\,}} + \left(8\,\cdot\, + \,\cdot\, + \frac{4\,\cdot\,(\,\cdot\,)}{\,}\right) \tag{10}$$

where $_* = \mathcal{R}(\mathbf{w}_*)$ *is the minimal risk.*

By choosing δ small enough, the last term in (10) that contains δ becomes non-dominating. To be specific, we have the following corollary.

Corollary 2 *By setting* $\,= 1\,$ *in Theorem* *1*, *we have* $(1\,\,\cdot\,) = 2\left(\log(2\,\cdot\,) + \,\log(6\,\cdot\,)\right)$, *and with high probability*

$$\mathcal{R}(\widehat{\mathbf{w}}) - \mathcal{R}(\mathbf{w}_*) = \left(\frac{\log\,}{\,} + \sqrt{\frac{\,_*}{\,}}\right) = \widetilde{\mathcal{O}}\left(\frac{\,}{\,} + \sqrt{\frac{\,_*}{\,}}\right)$$

Remark 2 The above corollary implies that under the smoothness and other common assumptions, ERM achieves an $\widetilde{\mathcal{O}}(\,+ \sqrt{\,_*}\,)$ risk bound for SCO. When the minimal risk is small, i.e., $_* = (\,^2\,)$, the rate is improved to $\widetilde{\mathcal{O}}(\,)$. Note that even under the smoothness assumption, the linear dependence on $\,$ is unavoidable ([Feldman], [2016], Theorem 3.7).

We next present excess risk bounds under both the smoothness and strong convexity conditions.

Theorem 3 *Under* **Assumptions** **1**, **2**, **3**, **4(b)**, **4(d)**, *and* **5**, *with probability at least* $1 - 2\delta$, *we have*

$$\mathcal{R}(\widehat{\mathbf{w}}) - \mathcal{R}(\mathbf{w}_*)$$

$$\frac{16\beta^2(\,\cdot\,)}{\,} + \frac{8\beta\log(2\,\cdot\,)}{\,} + \frac{8\,\cdot\,_*\log(2\,\cdot\,)}{\,} + \left(8\,\cdot\, + \,\cdot\, + \frac{4\,\cdot\,(\,\cdot\,)}{\,}\right) \tag{11}$$

Furthermore, if

$$\frac{4\,\cdot\,(\,\cdot\,)}{\,} = 4\,\cdot\,(\,\cdot\,) \tag{12}$$

we also have

$$\mathcal{R}(\widehat{\mathbf{w}}) - \mathcal{R}(\mathbf{w}_*)\,\, \frac{32\,\cdot\,^2\log^2(2\,\cdot\,)}{\,^2} + \frac{128\,\cdot\,_*\log(2\,\cdot\,)}{\,} + \left(\frac{128\,\cdot\,^2\,^2}{\,} + 16\,\cdot\, + 4\,\cdot\,^2\right) \tag{13}$$

The above theorem can be simplified by choosing different values of $\,$.

Corollary 4 *By setting* $\,= 1\,$ *in Theorem* *3*, *we have* $(1\,\,\cdot\,) = 2\left(\log(2\,\cdot\,) + \,\log(6\,\cdot\,)\right)$, *and with high probability*

$$\mathcal{R}(\widehat{\mathbf{w}}) - \mathcal{R}(\mathbf{w}_*) = \left(\frac{\log\,}{\,} + \frac{\,_*}{\,}\right) = \widetilde{\mathcal{O}}\left(\frac{\,}{\,} + \frac{\,_*}{\,}\right)$$

By setting $\,= 1\,^2$, *we have* $(1\,^2\,\cdot\,) = 2\left(\log(2\,\cdot\,) + \,\log(6\,^2\,\cdot\,)\right)$ *and when* $\,= \Omega(\,\log\,) = \widetilde{\Omega}(\,)$, *with high probability*

$$\mathcal{R}(\widehat{\mathbf{w}}) - \mathcal{R}(\mathbf{w}_*) = \left(\frac{1}{\,^2} + \frac{\,_*}{\,}\right)$$

Remark 3 The first part of Corollary 4 shows that ERM enjoys an $\widetilde{\ }(\ +\ _*\ )$ risk bound for stochastic optimization of strongly convex and smooth functions. In the literature, the most comparable result is the $(1\ )$ risk bound proved by Shalev-Shwartz et al. (2009) but with striking differences highlighted in Table 1. Since the risk bound of Shalev-Shwartz et al. (2009) is independent of the dimensionality

wh

zer. G

objective

We define

$$(\mathbf{w}) = \mathrm{E}_{(\mathbf{x},y}$$

to capture the stochastic component.

Besides **4(b)** and **4(c)**, we introduce the

notation $\cdot$ to denote the norm induced by the

Assumption 10 *Let* $\mathbf{w}_* \in \arg\min_{\mathbf{w} \in \mathcal{W}} \mathcal{R}(\mathbf{w})$ *be an optimal solution to (17). We assume the gradient of the random function at* $\mathbf{w}_*$ *is upper bounded by* γ*, that is,*

$$\|\nabla \ell(\mathbf{w}_*^\top \mathbf{x}, y)\| \le \gamma, \quad \forall (\mathbf{x}, y) \sim \mathbb{D} \tag{22}$$

Remark 7 The above assumptions allow us to model many popular losses in machine learning, such as (regularized) square loss and (regularized) logistic loss. **Assumptions 7** and **8** imply the random function $\ell(\cdot \mathbf{x}, y)$ is β^2-smooth over $\mathbf{W}$. To see this, for any $\mathbf{w}, \mathbf{w}' \in \mathbf{W}$, we have

$$\|\nabla \ell(\mathbf{w}^\top \mathbf{x}, y) - \nabla \ell(\mathbf{w}'^\top \mathbf{x}, y)\| = \|\ell'(\mathbf{w}^\top \mathbf{x}, y)\mathbf{x} - \ell'(\mathbf{w}'^\top \mathbf{x}, y)\mathbf{x}\|$$

$$\overset{(19)}{\le} |\ell'(\mathbf{w}^\top \mathbf{x}, y) - \ell'(\mathbf{w}'^\top \mathbf{x}, y)| \overset{(20)}{\le} \gamma |\mathbf{w}^\top \mathbf{x} - \mathbf{w}'^\top \mathbf{x}| \overset{(19)}{\le} \beta^2 \|\mathbf{w} - \mathbf{w}'\|$$

By Jensen's inequality, $\mathcal{R}(\cdot)$ is also β^2-smooth. Notice that β^2 is the modulus of smoothness of $\mathcal{R}(\cdot)$, and μ is the modulus of strong convexity of $\mathcal{R}(\cdot)$. With a slight abuse of notation, we define $\lambda = \beta^2$, and the condition number κ as the ratio between λ and μ, i.e., $\kappa = \lambda/\mu$. Finally, we note that the regularizer $g(\cdot)$ could be *non-smooth*.

We have the following excess risk bound of ERM for supervised learning.

Theorem 7 *For any* $0 < \delta, \tau \le 1/2$, *define*

$$C = 4 \left(8 + \sqrt{2 \log \frac{2 \log_2(\kappa) + \log_2(2/\tau)}{\delta}} \right) \tag{23}$$

$$\mathcal{R}_* = \mathcal{R}(\mathbf{w}_*) = \mathcal{F}(\mathbf{w}_*) - g(\mathbf{w}_*) \tag{24}$$

Under **Assumptions 4(b)**, **4(c)**, **6**, **7**, **8**, **9**, *and* **10** *with probability at least* $1 - 2\delta$, *we have*

$$\mathcal{R}(\widehat{\mathbf{w}}) - \mathcal{R}(\mathbf{w}_*) \le \max\left(\frac{\mathcal{R}_* + g_*}{n^2} + \frac{4 C^2 \beta^2 \gamma^2}{\mu^2 n^4} + \frac{4 \mathcal{R}_* \log(2/\tau)}{\mu n} + \frac{8 g_* \log(2/\tau)}{\mu n} \right) \tag{25}$$

Furthermore, if

$$\frac{16 C^2 \beta^2 \gamma^2}{\mu^2} = 16 C^2 \kappa^2 \gamma^2 \tag{26}$$

with probability at least $1 - 2\delta$, *we have*

$$\mathcal{R}(\widehat{\mathbf{w}}) - \mathcal{R}(\mathbf{w}_*) \le \max\left(\frac{\mathcal{R}_* + g_*}{n^2} + \frac{8 C^2 \beta^2 \log^2(2/\tau)}{\mu^2 n^4} + \frac{16 g_* \log(2/\tau)}{\mu n} \right) \tag{27}$$

Remark 8 The first part of Theorem 7 presents an $(1-\cdot)$ risk bound,[3] similar to the $(1-\cdot)$ risk bound of Sridharan et al. (2009). The second part is an $(1-[\cdot^2] + \cdot_*)$ risk bound, and in this case, the lower bound of n is $\Omega(\kappa^2)$, which is dimensionality-independent. Thus, Theorem 7 can be applied even when the dimensionality is infinite. Generally speaking, the regularizer $g(\cdot)$ is nonnegative, and thus $g_* \le \mathcal{R}_*$. So, the second bound is even better than those in Theorems 3 and 5. Finally, we note that Theorem 7 should be treated as a counterpart of Theorem 5 for supervised learning, because both of them do not rely on the individual convexity, i.e., **Assumption 4(d)**. One may wonder whether it is possible to derive a counterpart of Theorem 3, that is, whether it is possible to utilize the individual convexity to reduce the lower bound of n by a factor of κ. We will investigate this question as a future work.

---

3. For brevity, we treat C as a constant because it only has a *double* logarithmic dependence on n.

4. Analysis

We here present the key idea of our analysis and the proof of Theorem 1. The omitted ones can be found in appendices.

4.1. The Key Idea

By the convexity of $\widehat{\ }(\cdot)$ and the optimality condition of $\widehat{\mathbf{w}}$ (Boyd and Vandenberghe, 2004), we have

Lemma 1 *Under* **Assumptions 2** *and* **4(d)***, with probability at least* $1 - $ `

where the last step is due to

$$\|\widehat{\mathbf{w}} - \mathbf{w}_*\| \sqrt{\frac{(\ )(\ (\widehat{\mathbf{w}}) - \ (\mathbf{w}_*))}{\ }} \ \frac{(\ )\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{2} + \frac{(\widehat{\mathbf{w}}) - \ (\mathbf{w}_*)}{2} \tag{35}$$

$$\|\widehat{\mathbf{w}} - \mathbf{w}_*\| \sqrt{\frac{(\ )}{\ }} \ \frac{(\ )\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{2} + \frac{\ }{2} \tag{36}$$

From (34), we get

$$\frac{1}{2}(\ (\widehat{\mathbf{w}}) - \ (\mathbf{w}_*))$$

$$\frac{2 \ (\ )\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{\ } + \frac{2 \ \log(2\ )\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{\ } + \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\| \sqrt{\frac{8 \ _*\log(2\ )}{\ }}$$

$$+ 2 \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\| + \frac{\ }{2} + \frac{(\ )\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{\ }$$

$$^{(4)}\frac{8 \ ^2 \ (\ )}{\ } + \frac{4 \ \log(2\ )}{\ } + 4 \ \sqrt{\frac{2 \ _*\log(2\ )}{\ }} + \left(4 \ + \frac{\ }{2} + \frac{2 \ (\ )}{\ }\right)$$

which implies (10).

5. Conclusions and Future Work

In this paper, we study the excess risk of ERM for SCO. Our theoretical results show that it is possible to achieve $(1\ )$-type of risk bounds under (i) the smoothness and small minimal risk conditions (i.e., Theorem 1) or (ii) the smoothness and strong convexity conditions (i.e., the first part of Theorems 3, 5, and 7). A more exciting result is that when is large enough, ERM has $(1\ ^2)$-type of risk bounds under the smoothness, strong convexity, and small minimal risk conditions (i.e., the second part of Theorems 3, 5, and 7).

In the context of SCO, there remain many open problems about ERM.

1. Our current results are restricted to the Hilbert or Euclidean space, because the smoothness and strong convexity are defined in terms of the $_2$-norm. We will extend our analysis to other geometries in the future.
2. As mentioned in **Remark 3**, under the strong convexity condition, a dimensionality-independent risk bound, e.g., $\widetilde{\ }(\ )$ or $\widetilde{\ }(1\ )$, that holds with high probability is still missing.
3. As discussed in **Remark 8**, it is unclear whether the convexity of the loss can be exploited to improve the lower bound of in the second part of Theorem 7. Ideally, we expect that $= \Omega(\ )$ is sufficient to deliver an $(1\ [\ ^2] + \ _*\ )$ risk bound.
4. The $(1\ ^2)$-type of risk bounds require both the smoothness and strong convexity conditions. One may investigate whether strong convexity can be relaxed to other weaker conditions, such as exponential concavity (Hazan et al., 2007).

Finally, as far as we know, there are no $(1\ ^2)$-type of risk bounds for stochastic approximation (SA). We will try to establish such bounds for SA.

Appendix A. Proof of Lemma 1

We introduce Lemma 2 of Smale and Zhou (2007).

Lemma 3 *Let $\mathbf{H}$ be a Hilbert space and let ξ be a random variable with values in $\mathbf{H}$. Assume $\|\xi\| \le M$ almost surely. Denote $\sigma^2(\xi) = \mathrm{E}\left[\|\xi\|^2\right]$. Let $\{\xi_i\}_{i=1}^m$ be $(\quad)$ independent drawers of ξ. For any $0 < \delta < 1$, with confidence $1 - \delta$,*

$$\left\| \frac{1}{m} \sum_{i=1}^m [\xi_i - \mathrm{E}[\xi_i]] \right\| \le \frac{2 M \log(2/\delta)}{m} + \sqrt{\frac{2\sigma^2(\xi)\log(2/\delta)}{m}}$$

We first consider a fixed $\mathbf{w} \in \mathbf{N}(\mathbf{W})$. Since $\ell_i(\cdot)$ is L-smooth, we have

$$\|\nabla\ell_i(\mathbf{w}) - \nabla\ell_i(\mathbf{w}_*)\| \overset{(5)}{\le} L \|\mathbf{w} - \mathbf{w}_*\| \tag{37}$$

Because $\ell_i(\cdot)$ is both convex and L-smooth, by (2.1.7) of Nesterov (2004), we have

$$\|\nabla\ell_i(\mathbf{w}) - \nabla\ell_i(\mathbf{w}_*)\|^2 \le L(\ell_i(\mathbf{w}) - \ell_i(\mathbf{w}_*) - \nabla\ell_i(\mathbf{w}_*)^\top \mathbf{w} - \mathbf{w}_*)$$

Taking expectation over both sides, we have

$$\mathrm{E}\left[\|\nabla\ell_i(\mathbf{w}) - \nabla\ell_i(\mathbf{w}_*)\|^2\right] \le L(\ell(\mathbf{w}) - \ell(\mathbf{w}_*) - \nabla\ell(\mathbf{w}_*)^\top \mathbf{w} - \mathbf{w}_*) \le L(\ell(\mathbf{w}) - \ell(\mathbf{w}_*))$$

where the last inequality follows from the optimality condition of $\mathbf{w}_*$, i.e.,

$$\nabla\ell(\mathbf{w}_*)^\top \mathbf{w} - \mathbf{w}_* \ge 0 \quad \forall \mathbf{w} \in \mathbf{W}$$

Following Lemma 3, with probability at least $1 - \delta$, we have

$$\left\| \mathcal{L}(\mathbf{w}) - \mathcal{L}(\mathbf{w}_*) - [\widehat{\mathcal{L}}(\mathbf{w}) - \widehat{\mathcal{L}}(\mathbf{w}_*)] \right\|$$

$$= \left\| \mathcal{L}(\mathbf{w}) - \mathcal{L}(\mathbf{w}_*) - \frac{1}{n} \sum_{i=1}^{n} [\ell_i(\mathbf{w}) - \ell_i(\mathbf{w}_*)] \right\|$$

$$\leq \frac{2 \|\mathbf{w} - \mathbf{w}_*\| \log(2/\delta)}{} + \sqrt{\frac{2 (\mathcal{L}(\mathbf{w}) - \mathcal{L}(\mathbf{w}_*)) \log(2/\delta)}{}}$$

We obtain Lemma 1 by taking the union bound over all $\mathbf{w} \in \mathbf{N}(\mathbf{W})$. To this end, we need an upper bound of the covering number $|\mathbf{N}(\mathbf{W})|$.

Let $\mathbf{B}$ be an unit ball of d dimension, and $\mathbf{N}(\mathbf{B})$ be its ϵ-net with minimal cardinality. According to a standard volume comparison argument (Pisier, 1989), we have

$$\log |\mathbf{N}(\mathbf{B})| \leq \log \frac{3}{\epsilon}$$

Let $\mathbf{B}(\ )$ be a ball centered at origin with radius r. Since we assume $\mathbf{W} \subseteq \mathbf{B}(\ )$, it follows that

$$\log |\mathbf{N}(\mathbf{W})| \leq \log \left| \mathbf{N}\left(\mathbf{B}(\ ) \frac{}{2} \right) \right| \leq \log \frac{6}{\ }$$

where the first inequality is because the covering numbers are (almost) increasing by inclusion (Plan and Vershynin, 2013, (3.2)).

Appendix B. Proof of Lemma 2

To apply Lemma 3, we need an upper bound of $\mathrm{E}\left[\|\nabla \ell_i(\mathbf{w}_*)\|^2 \right]$. Since $\ell_i(\cdot)$ is β-smooth and nonnegative, from Lemma 4.1 of Srebro et al. (2010), we have

$$\|\nabla \ell_i(\mathbf{w}_*)\|^2 \leq 4 \beta \ell_i(\mathbf{w}_*)$$

and thus

$$\mathrm{E}\left[\|\nabla \ell_i(\mathbf{w}_*)\|^2 \right] \leq 4 \beta \mathrm{E}[\ell_i(\mathbf{w}_*)] = 4 \beta \mathcal{L}_*$$

From **Assumption 5**, we have $\|\nabla \ell_i(\mathbf{w}_*)\| \leq$. Then, according to Lemma 3, with probability at least $1 - \delta$, we have

$$\left\| \nabla \mathcal{L}(\mathbf{w}_*) - \nabla \widehat{\mathcal{L}}(\mathbf{w}_*) \right\| = \left\| \nabla \mathcal{L}(\mathbf{w}_*) - \frac{1}{n} \sum_{i=1}^{n} \nabla \ell_i(\mathbf{w}_*) \right\| \leq \frac{2 \log(2/\delta)}{} + \sqrt{\frac{8 \beta \mathcal{L}_* \log(2/\delta)}{}}$$

Appendix C. Proof of Theorem 3

The proof follows the same logic as that of Theorem 1. Under **Assumption 4(b)**, (30) becomes

$$\mathcal{L}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*) + \frac{\mu}{2} \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

$$\leq \left(\underbrace{\left\| \nabla \mathcal{L}(\widehat{\mathbf{w}}) - \nabla \mathcal{L}(\mathbf{w}_*) - [\nabla \widehat{\mathcal{L}}(\widehat{\mathbf{w}}) - \nabla \widehat{\mathcal{L}}(\mathbf{w}_*)] \right\|}_{:=A_1} + \underbrace{\left\| \nabla \mathcal{L}(\mathbf{w}_*) - \nabla \widehat{\mathcal{L}}(\mathbf{w}_*) \right\|}_{:=A_2} \right) \|\widehat{\mathbf{w}} - \mathbf{w}_*\|$$

$$(38)$$

16

Substituting (32) and (33) into (38), with probability at least $1 - 2$, we have

$$
\begin{aligned}
&(\widehat{\mathbf{w}}) - \ (\mathbf{w}_*) + \frac{}{2}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 \\
&\quad \frac{(\ )\,\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\ \sqrt{\frac{(\ )(\ (\widehat{\mathbf{w}}) - \ (\mathbf{w}_*))}{}} \\
&\quad + \frac{2\ \log(2\ )\,\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} + \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\ \sqrt{\frac{8\ _*\log(2\ )}{}} \\
&\quad + 2\ \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\| + \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\ \sqrt{\frac{(\ )}{}} + \frac{(\ )\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{}
\end{aligned}
\tag{39}
$$

To prove (11), we substitute (35), (36), and

$$
\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\ \sqrt{\frac{8\ _*\log(2\ )}{}}\quad \frac{4\ _*\log(2\ )}{} + \frac{}{2}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
$$

into (39), and then obtain

$$
\begin{aligned}
&\frac{1}{2}(\ (\widehat{\mathbf{w}}) - \ (\mathbf{w}_*)) \\
&\quad \frac{2\ (\ )\,\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \frac{2\ \log(2\ )\,\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} + \frac{4\ _*\log(2\ )}{} \\
&\quad + 2\ \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\| + \frac{}{2} + \frac{(\ )\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} \\
&\quad ^{(4)}\ \frac{8\ ^2\,(\ )}{} + \frac{4\ \ \log(2\ )}{} + \frac{4\ _*\log(2\ )}{} + \left(4\ \ + \frac{}{2} + \frac{2\ \ (\ )}{} \right)
\end{aligned}
$$

which implies (11).

To prove (13), we substitute

$$
\begin{aligned}
&\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\ \sqrt{\frac{(\ )(\ (\widehat{\mathbf{w}}) - \ (\mathbf{w}_*))}{}}\quad \frac{2\ (\ )(\ (\widehat{\mathbf{w}}) - \ (\mathbf{w}_*))}{} + \frac{}{8}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 \\
&\qquad \frac{2\ \log(2\ )\,\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{}\quad \frac{16\ ^2\log^2(2\ )}{2} + \frac{}{16}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 \\
&\qquad \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\ \sqrt{\frac{8\ _*\log(2\ )}{}}\quad \frac{64\ _*\log(2\ )}{} + \frac{}{32}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 \\
&\qquad 2\ \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\quad \frac{64\ ^2\ ^2}{} + \frac{}{64}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 \\
&\qquad \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\ \sqrt{\frac{(\ )}{}}\quad \frac{32\ \ (\ )}{} + \frac{}{128}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 \\
&\qquad \frac{(\ )\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{}\quad \frac{32\ ^2\ ^2(\ )^2}{2} + \frac{}{128}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
\end{aligned}
$$

into (39), and then obtain

$$
\mathcal{L}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*) + \frac{}{4} \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
$$

$$
\frac{(\;)\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \frac{2\;(\;)(\mathcal{L}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*))}{} + \frac{16\;^2\log^2(2\;)}{^2} + \frac{64\;_*\log(2\;)}{}
$$

$$
+ \frac{64\;^2\;^2}{} + \frac{32\;(\;)}{} + \frac{32\;^2\;^2(\;)\;^2}{^2}
$$

$$
\overset{(12)}{} \frac{}{4}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 + \frac{1}{2}(\mathcal{L}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*)) + \frac{16\;^2\log^2(2\;)}{^2} + \frac{64\;_*\log(2\;)}{}
$$

$$
+ \frac{64\;^2\;^2}{} + 8\; + 2\;^2
$$

which implies (13).

Appendix D. Proof of Theorem 5

Without **Assumption 4(d)**, Lemma 1 which is used in the proofs of Theorems 1 and 3 does not hold anymore. Instead, we will use the following version that only relies on the smoothness condition.

Lemma 4 *Under* **Assumption 2**, *with probability at least* $1 - $, *for any* $\mathbf{w} \quad \mathbf{N}(\mathbf{W}\;)$, *we have*

$$
\left\| \nabla\mathcal{L}(\mathbf{w}) - \nabla\mathcal{L}(\mathbf{w}_*) - [\nabla\widehat{\mathcal{L}}(\mathbf{w}) - \nabla\widehat{\mathcal{L}}(\mathbf{w}_*)]\right\| \quad \frac{(\;)\|\mathbf{w} - \mathbf{w}_*\|}{} + \|\mathbf{w} - \mathbf{w}_*\|\sqrt{\frac{(\;)}{}}
$$

where $(\;)$ *is define in (9).*

The above lemma is a direct consequence of (37), Lemma 3 and the union bound.

The rest of the proof is similar to those of Theorems 1 and 3. We first derive a counterpart of (32) under Lemma 4. Combining (31) with Lemma 4, with probability at least $1 - $, we have

$$
\left\| \nabla\mathcal{L}(\widehat{\mathbf{w}}) - \nabla\mathcal{L}(\mathbf{w}_*) - [\nabla\widehat{\mathcal{L}}(\widehat{\mathbf{w}}) - \nabla\widehat{\mathcal{L}}(\mathbf{w}_*)]\right\|
$$

$$
\frac{(\;)\|\widetilde{\mathbf{w}} - \mathbf{w}_*\|}{} + \|\widetilde{\mathbf{w}} - \mathbf{w}_*\|\sqrt{\frac{(\;)}{}} + 2
$$

$$
\frac{(\;)\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} + \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\sqrt{\frac{(\;)}{}} + \frac{(\;)}{} + \sqrt{\frac{(\;)}{}} + 2
$$
(40)

Substituting (40) and (33) into (38), with probability at least $1 - 2\;$, we have

$$
\mathcal{L}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*) + \frac{}{2}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
$$

$$
\frac{(\;)\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2\sqrt{\frac{(\;)}{}}
$$

$$
+ \frac{2\;\log(2\;)\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} + \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\sqrt{\frac{8\;_*\log(2\;)}{}}
$$
(41)

$$
+ 2\;\|\widehat{\mathbf{w}} - \mathbf{w}_*\| + \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\sqrt{\frac{(\;)}{}} + \frac{(\;)\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{}
$$

18

To get (14), we substitute

$$\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 \sqrt{\frac{(\cdot,\cdot)}{}} \quad \frac{^2 \ (\cdot,\cdot)\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \frac{}{4}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

$$\|\widehat{\mathbf{w}} - \mathbf{w}_*\| \sqrt{\frac{8 \ *\log(2\cdot)}{}} \quad \frac{8 \ *\log(2\cdot)}{} + \frac{}{4}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

into (41), and then obtain

$$(\widehat{\mathbf{w}}) - \ (\mathbf{w}_*)$$

$$\frac{(\cdot,\cdot)\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \frac{^2 \ (\cdot,\cdot)\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \frac{2 \ \log(2\cdot)\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} + \frac{8 \ *\log(2\cdot)}{}$$

$$+\,2 \quad \|\widehat{\mathbf{w}} - \mathbf{w}_*\| + \quad \|\widehat{\mathbf{w}} - \mathbf{w}_*\| \sqrt{\frac{(\cdot,\cdot)}{}} + \frac{(\cdot,\cdot)\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{}$$

$$\overset{(4)}{} \frac{4 \ ^2 \ (\cdot,\cdot)}{} + \frac{4 \ ^2 \ ^2 \ (\cdot,\cdot)}{} + \frac{4 \ \log(2\cdot)}{} + \frac{8 \ *\log(2\cdot)}{}$$

$$+ \left(4 \quad + 2 \quad \sqrt{\frac{(\cdot,\cdot)}{}} + \frac{2 \quad (\cdot,\cdot)}{}\right)$$

which proves (14).

To get (16), we substitute

$$\frac{2 \ \log(2\cdot)\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} \quad \frac{8 \ ^2\log^2(2\cdot)}{^2} + \frac{}{8}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

$$\|\widehat{\mathbf{w}} - \mathbf{w}_*\| \sqrt{\frac{8 \ *\log(2\cdot)}{}} \quad \frac{32 \ *\log(2\cdot)}{} + \frac{}{16}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

$$2 \quad \|\widehat{\mathbf{w}} - \mathbf{w}_*\| \quad \frac{32 \ ^2 \ ^2}{} + \frac{}{32}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

$$\|\widehat{\mathbf{w}} - \mathbf{w}_*\| \sqrt{\frac{(\cdot,\cdot)}{}} \quad \frac{16 \ ^2 \ (\cdot,\cdot)^2}{} + \frac{}{64}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

$$\frac{(\cdot,\cdot)\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} \quad \frac{16 \ ^2 \ ^2( )^2}{^2} + \frac{}{64}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

into (41), and then obtain

$$(\widehat{\mathbf{w}}) - \ (\mathbf{w}_*) + \frac{}{4}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

$$\frac{(\cdot,\cdot)\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 \sqrt{\frac{(\cdot,\cdot)}{}} + \frac{8 \ ^2\log^2(2\cdot)}{^2} + \frac{32 \ *\log(2\cdot)}{}$$

$$+ \left(\frac{32 \ ^2}{} + \frac{16 \ ^2 \ (\cdot,\cdot)}{} + \frac{16 \ ^2 \ ^2( )}{^2}\right) \ ^2$$

$$\overset{(15)}{} \frac{^2 \ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{25} + \frac{}{5}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 + \frac{8 \ ^2\log^2(2\cdot)}{2} + \frac{32 \ *\log(2\cdot)}{}$$

$$+ \left(\frac{32 \ ^2}{} + \frac{16}{25} + \frac{16 \ ^3}{625 \ ^2}\right) \ ^2$$

$$\overset{\lambda/L \le 1}{} \frac{6}{25}\ \|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 + \frac{8 \ ^2\log^2(2\cdot)}{2} + \frac{32 \ *\log(2\cdot)}{} + \left(\frac{32 \ ^2}{} + \frac{416}{625}\right) \ ^2$$

By subtracting $\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 / 4$ from both sides we complete the proof of (16).

Appendix E. Proof of Theorem 7

We consider two cases. In the first case, we assume that

$$\|\widehat{\mathbf{w}} - \mathbf{w}_*\| \geq \frac{1}{2}$$

Since $\ell(\cdot)$ is β-smooth and $\ell(\cdot)$ is ρ-Lipschitz continuous, we have

$$\mathcal{L}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*) = \mathcal{L}(\widehat{\mathbf{w}}) + \mathcal{R}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*) - \mathcal{R}(\mathbf{w}_*)$$

$$\leq \langle \widehat{\mathbf{w}} - \mathbf{w}_*, \nabla\mathcal{L}(\mathbf{w}_*)\rangle + \frac{\beta}{2}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 + \rho\|\widehat{\mathbf{w}} - \mathbf{w}_*\| \tag{42}$$

$$\leq \langle \widehat{\mathbf{w}} - \mathbf{w}_*, \nabla\mathcal{L}(\mathbf{w}_*)\rangle + \frac{\beta}{2}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 + \rho\|\widehat{\mathbf{w}} - \mathbf{w}_*\| \leq \frac{\rho + \beta}{2} + \frac{\beta}{2} \cdot 4$$

where the last step utilizes Jensen's inequality

$$\|\nabla\mathcal{L}(\mathbf{w}_*)\| = \left\|\mathrm{E}_{(\mathbf{x},y)\sim\mathbb{D}}[\ell'(\mathbf{w}_*^\top\mathbf{x})]\right\| \leq \mathrm{E}_{(\mathbf{x},y)\sim\mathbb{D}}[\ell'(\mathbf{w}_*^\top\mathbf{x})] \tag{22}$$

Next, we study the case

$$\frac{1}{2} \geq \|\widehat{\mathbf{w}} - \mathbf{w}_*\| \overset{(18)}{\geq} 2$$

From (29), we have

$$\mathcal{L}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*) + \frac{\beta}{2}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2$$

$$\leq \mathcal{L}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*) - [\nabla\widehat{\mathcal{L}}(\widehat{\mathbf{w}}) - \nabla\widehat{\mathcal{L}}(\mathbf{w}_*)]\|\widehat{\mathbf{w}} - \mathbf{w}_*\| + \langle\nabla\mathcal{L}(\mathbf{w}_*) - \nabla\widehat{\mathcal{L}}(\mathbf{w}_*)\rangle\|\widehat{\mathbf{w}} - \mathbf{w}_*\|$$

$$= \mathcal{L}(\widehat{\mathbf{w}}) - \mathcal{L}(\mathbf{w}_*) - [\nabla\widehat{\mathcal{L}}(\widehat{\mathbf{w}}) - \nabla\widehat{\mathcal{L}}(\mathbf{w}_*)]\|\widehat{\mathbf{w}} - \mathbf{w}_*\| + \langle\nabla\mathcal{L}(\mathbf{w}_*) - \nabla\widehat{\mathcal{L}}(\mathbf{w}_*)\rangle\|\widehat{\mathbf{w}} - \mathbf{w}_*\|$$

$$\leq \underbrace{\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\|\widehat{\mathbf{w}}-\mathbf{w}_*\|}\left\langle\nabla\mathcal{L}(\mathbf{w}) - \nabla\mathcal{L}(\mathbf{w}_*) - [\nabla\widehat{\mathcal{L}}(\mathbf{w}) - \nabla\widehat{\mathcal{L}}(\mathbf{w}_*)], \mathbf{w} - \mathbf{w}_*\right\rangle}_{:=B_1}$$

$$+ \underbrace{\left\|\nabla\mathcal{L}(\mathbf{w}_*) - \nabla\widehat{\mathcal{L}}(\mathbf{w}_*)\right\|}_{:=B_2}\|\widehat{\mathbf{w}} - \mathbf{w}_*\| \tag{43}$$

We first bound B_1. To utilize the fact the random variable $\|\widehat{\mathbf{w}} - \mathbf{w}_*\|$ lies in the range $(1, 2^{-2} \cdot 2]$, we develop the following lemma.

Lemma 5 *Under* **Assumptions 7** *and* **8***, with probability at least $1 - \delta$, for all*

$$\frac{1}{2} \leq \gamma \leq 2$$

the following bound holds:

$$\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma}\left\langle\nabla\mathcal{L}(\mathbf{w}) - \nabla\mathcal{L}(\mathbf{w}_*) - [\nabla\widehat{\mathcal{L}}(\mathbf{w}) - \nabla\widehat{\mathcal{L}}(\mathbf{w}_*)], \mathbf{w} - \mathbf{w}_*\right\rangle \leq \frac{4\gamma^2}{\sqrt{n}}\left(8 + \sqrt{2\log\frac{\zeta}{\delta}}\right)$$

where $\zeta = 2\log_2(n) + \log_2(2\gamma)$.

Based on the above lemma, we have with probability at least $1 - \delta$,

$$
\frac{4}{\gamma_1}\frac{\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{-}\left(8 + \sqrt{2\log\frac{-}{\delta}}\right) = \frac{\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{-} \tag{44}
$$

where γ is defined in (23).

We then proceed to handle A_2, which can be upper bounded in the same way as A_2. In particular, we have the following lemma.

Lemma 6 *Under* **Assumptions 7, 8,** *and* **10,** *with probability at least* $1 - \delta$*, we have*

$$
\left\| \nabla(\mathbf{w}_*) - \widehat{\nabla}(\mathbf{w}_*) \right\| \frac{2\log(2/\delta)}{} + \sqrt{\frac{8\sigma_* \log(2/\delta)}{}} \tag{45}
$$

Substituting (44) and (45) into (43), with probability at least $1 - 2\delta$, we have

$$
\nabla(\widehat{\mathbf{w}}) - \nabla(\mathbf{w}_*) + \frac{\gamma}{2}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
$$
$$
\frac{\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{-} + \frac{2\log(2/\delta)\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} + \|\widehat{\mathbf{w}} - \mathbf{w}_*\|\sqrt{\frac{8\sigma_* \log(2/\delta)}{}} \tag{46}
$$

We substitute

$$
\frac{\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{-} \frac{2\gamma^2\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \frac{\gamma}{4}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
$$
$$
\|\widehat{\mathbf{w}} - \mathbf{w}_*\|\sqrt{\frac{8\sigma_* \log(2/\delta)}{}} \frac{8\sigma_* \log(2/\delta)}{} + \frac{\gamma}{4}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
$$

into (46), and then have

$$
\nabla(\widehat{\mathbf{w}}) - \nabla(\mathbf{w}_*) \frac{2\gamma^2\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{} + \frac{2\log(2/\delta)\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} + \frac{8\sigma_* \log(2/\delta)}{}
$$
$$
\overset{(18)}{} \frac{4\gamma^2}{} + \frac{4\log(2/\delta)}{} + \frac{8\sigma_* \log(2/\delta)}{}
$$

Combining the above inequality with (42), we obtain (25).

To prove (27), we substitute

$$
\frac{2\log(2/\delta)\|\widehat{\mathbf{w}} - \mathbf{w}_*\|}{} \frac{8\gamma^2\log^2(2/\delta)}{\gamma^2} + \frac{\gamma}{8}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
$$
$$
\|\widehat{\mathbf{w}} - \mathbf{w}_*\|\sqrt{\frac{8\sigma_* \log(2/\delta)}{}} \frac{16\sigma_* \log(2/\delta)}{} + \frac{\gamma}{8}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
$$

into (46), and then have

$$
\nabla(\widehat{\mathbf{w}}) - \nabla(\mathbf{w}_*) + \frac{\gamma}{4}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2
$$
$$
\frac{\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2}{-} + \frac{8\gamma^2\log^2(2/\delta)}{\gamma^2} + \frac{16\sigma_* \log(2/\delta)}{}
$$
$$
\overset{(26)}{} \frac{\gamma}{4}\|\widehat{\mathbf{w}} - \mathbf{w}_*\|^2 + \frac{8\gamma^2\log^2(2/\delta)}{\gamma^2} + \frac{16\sigma_* \log(2/\delta)}{}
$$

Combining the above inequality with (42), we obtain (27).

21

Appendix F. Proof of Lemma 5

First, we partition the range $(1 \quad {}^2 2 \quad]$ into $\quad = \quad 2\log_2(\;) + \log_2(2 \quad)$ consecutive segments $\Delta_1 \; \Delta_2 \quad \Delta_s$ such that

$$\Delta_k = \left(\underbrace{\frac{2^{k-1}}{2}}_{:=\gamma_k^-} \; \underbrace{\frac{2^k}{2}}_{:=\gamma_k^+} \right] \quad = 1$$

Then, we consider the case $\quad \Delta_k$ for a fixed value of $\;$. We have

$$
\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma} \left\langle \quad (\mathbf{w}) - \quad (\mathbf{w}_*) - [\quad \widehat{\;}(\mathbf{w}) - \quad \widehat{\;}(\mathbf{w}_*)] \; \mathbf{w} - \mathbf{w}_* \right\rangle
$$
$$
\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+} \left\langle \quad (\mathbf{w}) - \quad (\mathbf{w}_*) - [\quad \widehat{\;}(\mathbf{w}) - \quad \widehat{\;}(\mathbf{w}_*)] \; \mathbf{w} - \mathbf{w}_* \right\rangle
\tag{47}
$$

Based on the McDiarmid's inequality (McDiarmid, 1989) and the Rademacher complexity (Bartlett and Mendelson, 2002), we have the following lemma to upper bound the last term.

Lemma 7 *Under* **Assumptions 7** *and* **8***, with probability at least* $1 - \;$, *we have*

$$
\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+} \left\langle \quad (\mathbf{w}) - \quad (\mathbf{w}_*) - [\quad \widehat{\;}(\mathbf{w}) - \quad \widehat{\;}(\mathbf{w}_*)] \; \mathbf{w} - \mathbf{w}_* \right\rangle
$$
$$
\frac{(\quad_k^+)^2}{=} \left(8 + \sqrt{2\log\frac{1}{\;}} \right)
\tag{48}
$$

Since $\quad \Delta_k$, we have

$$
\quad_k^+ = 2 \quad_k^- \quad 2
\tag{49}
$$

Thus, with probability at least $1 - \;$, we have

$$
\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma} \left\langle \quad (\mathbf{w}) - \quad (\mathbf{w}_*) - [\quad \widehat{\;}(\mathbf{w}) - \quad \widehat{\;}(\mathbf{w}_*)] \; \mathbf{w} - \mathbf{w}_* \right\rangle
$$
$$
\overset{(47),(48),(49)}{\quad} \frac{4 \quad ^2}{=} \left(8 + \sqrt{2\log\frac{1}{\;}} \right)
$$

We complete the proof by taking the union bound over $\quad$ segments.

Appendix G. Proof of Lemma 7

To simplify the notation, we define

$$
\quad_i(\mathbf{w}) = (\quad \mathbf{w} \; \mathbf{x}_i \quad_i) \quad = 1
$$
$$
(\quad_1 \quad \quad_n) = \sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+} \left\langle \quad (\mathbf{w}) - \quad (\mathbf{w}_*) - \frac{1}{\quad}\sum_{i=1}^{n}[\quad_i(\mathbf{w}) - \quad_i(\mathbf{w}_*)] \; \mathbf{w} - \mathbf{w}_* \right\rangle
$$

To upper bound $(\quad_1 \quad \quad_n)$, we utilize the McDiarmid's inequality (McDiarmid, 1989).

Theorem 8 *Let $h_1, \ldots, h_n$ be independent random variables taking values in a set A, and assume that $\Phi : A^n \to \mathbb{R}$ satisfies*

$$\sup_{x_1,\ldots,x_n,x_i' \in A} \left| \Phi(x_1,\ldots,x_n) - \Phi(x_1,\ldots,x_{i-1},x_i',x_{i+1},\ldots,x_n) \right| \leq c_i$$

for every $1 \leq i \leq n$. Then, for every $t > 0$,

$$\mathbb{P}\left\{ \Phi(x_1,\ldots,x_n) - \mathrm{E}[\Phi(x_1,\ldots,x_n)] \geq t \right\} \leq \exp\left(-\frac{2t^2}{\sum_{i=1}^{n} c_i^2} \right)$$

As pointed out in **Remark 7**, **Assumptions 7** and **8** imply the random function $\ell_i(\cdot)$ is β-smooth, and thus

$$\left| \ell_i(\mathbf{w}) - \langle \nabla \ell_i(\mathbf{w}_*), \mathbf{w} - \mathbf{w}_* \rangle \right| \leq \beta \|\mathbf{w} - \mathbf{w}_*\|^2 \leq \beta (\gamma_k^+)^2$$

As a result, when a random function ℓ_i changes, the random variable $\Phi(x_1,\ldots,x_n)$ can change by no more than $2\beta (\gamma_k^+)^2 / n$. To see this, we have

$$\Phi(x_1,\ldots,x_n) - \Phi(x_1,\ldots,x_{i-1},x_i',x_{i+1},\ldots,x_n)$$
$$\leq \frac{1}{n} \sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\| \leq \gamma_k^+} \left\langle \nabla \ell_i'(\mathbf{w}) - \nabla \ell_i'(\mathbf{w}_*) - [\nabla \ell_i(\mathbf{w}) - \nabla \ell_i(\mathbf{w}_*)], \mathbf{w} - \mathbf{w}_* \right\rangle \leq \frac{2\beta}{n} (\gamma_k^+)^2$$

McDiarmid's inequality implies that with probability at least $1 - \delta$,

$$\Phi(x_1,\ldots,x_n) \leq \mathrm{E}[\Phi(x_1,\ldots,x_n)] + \beta (\gamma_k^+)^2 \sqrt{\frac{2}{n} \log \frac{1}{\delta}} \tag{50}$$

Let $(h_1',\ldots,h_n')$ be an independent copy of $(h_1,\ldots,h_n)$, and $\sigma_1,\ldots,\sigma_n$ be i.i.d. Rademacher variables with equal probability of being ± 1. Using techniques of Rademacher complexities ([Bartlett and Mendelson, 2002](#)), we bound $\mathrm{E}[\Phi(x_1,\ldots,x_n)]$ as follows:

$$\mathrm{E}_{h_1,\ldots,h_n} \left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\| \leq \gamma_k^+} \left\langle \nabla \mathcal{L}(\mathbf{w}) - \nabla \mathcal{L}(\mathbf{w}_*) - \frac{1}{n} \sum_{i=1}^{n} [\nabla \ell_i(\mathbf{w}) - \nabla \ell_i(\mathbf{w}_*)], \mathbf{w} - \mathbf{w}_* \right\rangle \right]$$

$$= \frac{1}{n} \mathrm{E}_{h_1,\ldots,h_n} \left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\| \leq \gamma_k^+} \right.$$

$$\mathrm{E}_{h_1',\ldots,h_n'} \left[\sum_{i=1}^{n} \left\langle \nabla \ell_i'(\mathbf{w}) - \nabla \ell_i'(\mathbf{w}_*), \mathbf{w} - \mathbf{w}_* \right\rangle \right] - \sum_{i=1}^{n} \left\langle \nabla \ell_i(\mathbf{w}) - \nabla \ell_i(\mathbf{w}_*), \mathbf{w} - \mathbf{w}_* \right\rangle \right]$$

$$\leq \frac{1}{n} \mathrm{E}_{h_1,\ldots,h_n,h_1',\ldots,h_n'} \left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\| \leq \gamma_k^+} \right.$$

$$\left. \sum_{i=1}^{n} \left\langle \nabla \ell_i'(\mathbf{w}) - \nabla \ell_i'(\mathbf{w}_*), \mathbf{w} - \mathbf{w}_* \right\rangle - \sum_{i=1}^{n} \left\langle \nabla \ell_i(\mathbf{w}) - \nabla \ell_i(\mathbf{w}_*), \mathbf{w} - \mathbf{w}_* \right\rangle \right]$$

$$= \frac{1}{n} E_{h_1,\ldots,h_n,h'_1,\ldots,h'_n,\epsilon_1,\ldots,\epsilon_n} \left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+} \right.$$

$$\sum_i^n$$

Note that $\cdot^2$ is 2-Lipschitz over $[-,\ ]$, and $\ell_i(\mathbf{w})+\ell_i(\mathbf{w})\in[-2\gamma_k^+\ -\ 2\gamma_k^+\ ]$. Then, from the comparison theorem of Rademacher complexities (Ledoux and Talagrand, 1991), in particular Lemma 5 of Meir and Zhang (2003), we have

$$
\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\left(\ell_i(\mathbf{w})+\ell_i(\mathbf{w})\right)^2\right]
$$

$$
4\gamma_k^+\sqrt{}\,\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\left(\ell_i(\mathbf{w})+\ell_i(\mathbf{w})\right)\right] \tag{53}
$$

$$
4\gamma_k^+\sqrt{}\,\left(\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\ell_i(\mathbf{w})\right]+\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\ell_i(\mathbf{w})\right]\right)
$$

Similarly, we have

$$
\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\left(\ell_i(\mathbf{w})-\ell_i(\mathbf{w})\right)^2\right]
$$

$$
4\gamma_k^+\sqrt{}\,\left(\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\ell_i(\mathbf{w})\right]+\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\ell_i(\mathbf{w})\right]\right) \tag{54}
$$

Combining (52), (53), and (54), we arrive at

$$
\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\left(\ell_i(\mathbf{w})-\ell_i(\mathbf{w}_*)\right)\mathbf{w}-\mathbf{w}_*\right]
$$

$$
2\gamma_k^+\sqrt{}\,\left(\underbrace{\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\ell_i(\mathbf{w})\right]}_{:=C_1}+\underbrace{\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\ell_i(\mathbf{x})\right]}_{:=C_2}\right) \tag{55}
$$

We proceed to upper bound C_1 in (55). From our definition of $\ell_i(\mathbf{w})$, we have

$$
\left|\ell_i(\mathbf{w})-\ell_i(\mathbf{w}')\right|=\frac{1}{}\left|\ell'(\mathbf{w}\cdot\mathbf{x}_i\ i)-\ell'(\mathbf{w}'\cdot\mathbf{x}_i\ i)\right|
$$

$$
\sqrt{}\,\left|\mathbf{w}\cdot\mathbf{x}_i\ -\ \mathbf{w}'\cdot\mathbf{x}_i\right|=\sqrt{}\,\left|\mathbf{x}_i\ \mathbf{w}-\mathbf{w}_*\ -\ \mathbf{x}_i\ \mathbf{w}'-\mathbf{w}_*\right|
$$

Applying the comparison theorem of Rademacher complexities again, we have

$$
C_1\ \sqrt{}\,\mathrm{E}\left[\sup_{\mathbf{w}:\|\mathbf{w}-\mathbf{w}_*\|\leq\gamma_k^+}\sum_{i=1}^{n}\sigma_i\ \mathbf{x}_i\ \mathbf{w}-\mathbf{w}_*\right]=\ C_2 \tag{56}
$$

Zhang Yang
